CHAPTER

ONE

PALO ALTO FIREWALL NIST 800.53 V5

1.1 Terms of Use

1.2 AC-1

1.2.1 Control or Control Name

Policy and Procedures

1.2.2 Control Text

a. Develop, document, and disseminate to [Assignment: organization-defined personnel or roles]: 1. [Selection (one or more): organization-level; mission/business process-level; system-level] access control policy that: (a) Addresses purpose, scope, roles, responsibilities, management commitment, coordination among organizational entities, and compliance; and (b) Is consistent with applicable laws, executive orders, directives, regulations, policies, standards, and guidelines; and 2. Procedures to facilitate the implementation of the access control policy and the associated access controls; b. Designate an [Assignment: organization-defined official] to manage the development, documentation, and dissemination of the access control policy and procedures; and c. Review and update the current access control: 1. Policy [Assignment: organization-defined frequency]; and 2. Procedures [Assignment: organization-defined frequency].

1.2.3 Discussion

This control addresses policy and procedures for the controls in the AC family implemented within systems and organizations. The risk management strategy is an important factor in establishing such policies and procedures. Policies and procedures help provide security and privacy assurance. Therefore, it is important that security and privacy programs collaborate on their development. Security and privacy program policies and procedures at the organization level are preferable, in general, and may obviate the need for system-specific policies and procedures. The policy can be included as part of the general security and privacy policy or can be represented by multiple policies reflecting the complex nature of organizations. Procedures can be established for security and privacy programs and for systems, if needed. Procedures describe how the policies or controls are implemented and can be directed at the individual or role that is the object of the procedure. Procedures can be documented in system security and privacy plans or in one or more separate documents. Restating controls does not constitute an organizational policy or procedure.

1.3 AC-2

1.3.1 Control or Control Name

Account Management

1.3.2 Control Text

a. Define and document the types of accounts allowed for use within the system;

b. Assign account managers;

c. Establish conditions for group and role membership;

d. Specify: 1. Authorized users of the system; 2. Group and role membership; and 3. Access authorizations (i.e., privileges) and [Assignment: organization-defined attributes (as required)] for each account; e. Require approvals by [Assignment: organization-defined personnel or roles] for requests to create accounts; f. Create, enable, modify, disable, and remove accounts in accordance with [Assignment: organization-defined policy, procedures, and conditions]; g. Monitor the use of accounts; h. Notify account managers and [Assignment: organization-defined personnel or roles] within: 1. [Assignment: organization-defined time-period] when accounts are no longer required; 2. [Assignment: organization-defined time-period] when users are terminated or transferred; and 3. [Assignment: organization-defined time-period] when system usage or need-to-know changes for an individual; i. Authorize access to the system based on: 1. A valid access authorization; 2. Intended system usage; and 3. [Assignment: organization-defined attributes (as required)]; j. Review accounts for compliance with account management requirements [Assignment: organization-defined frequency]; k. Establish and implement a process for changing shared or group account credentials (if deployed) when individuals are removed from the group; and l. Align account management processes with personnel termination and transfer processes.

1.3.3 Discussion

Examples of system account types include individual, shared, group, system, guest, anonymous, emergency, developer, temporary, and service. Identification of authorized system users and the specification of access privileges reflects the requirements in other controls in the security plan. Users requiring administrative privileges on system accounts receive additional scrutiny by organizational personnel responsible for approving such accounts and privileged access, including system owner, mission or business owner, senior agency information security officer, or senior agency official for privacy. External system accounts are not included in the scope of this control. Organizations address external system accounts through organizational policy. Where access involves personally identifiable information, security programs collaborate with the senior agency official for privacy on establishing the specific conditions for group and role membership; specifying for each account, authorized users, group and role membership, and access authorizations; and creating, adjusting, or removing system accounts in accordance with organizational policies. Policies can include such information as account expiration dates or other factors triggering the disabling of accounts. Organizations may choose to define access privileges or other attributes by account, by type of account, or a combination of the two. Examples of other attributes required for authorizing access include restrictions on time-of-day, day-of-week, and point-of-origin. In defining other system account attributes, organizations consider system-related requirements and mission/business requirements. Failure to consider these factors could affect system availability. Temporary and emergency accounts are intended for short-term use. Organizations establish temporary accounts as a part of normal account activation procedures when there is a need for short-term accounts without the demand for immediacy in account activation. Organizations establish emergency accounts in response to crisis situations and with the need for rapid account activation. Therefore, emergency account activation may bypass normal account authorization processes. Emergency and temporary accounts are not to be confused with infrequently used accounts, including local logon accounts used for special tasks or when network resources are unavailable (may also be known as accounts of last resort). Such accounts remain available and are not subject to automatic disabling or removal dates. Conditions for disabling or deactivating accounts include when shared/group, emergency, or temporary accounts are no longer required; and when individuals are transferred or terminated. Changing shared/group account credentials when members leave the group is intended to ensure that former group members do not retain access to the shared or group account. Some types of system accounts may require specialized training.

1.3.4 Related Controls

1.9 Control or Control Enhancement Identifier

AC-2(6)

1.9.1 Control or Control Name

Account Management | Dynamic Privilege Management

1.9.2 Control Text

Implement [Assignment: organization-defined dynamic privilege management capabilities].

1.9.3 Discussion

In contrast to access control approaches that employ static accounts and predefined user privileges, dynamic access control approaches rely on run time access control decisions facilitated by dynamic privilege management such as attribute-based access control. While user identities remain relatively constant over time, user privileges typically change more frequently based on ongoing mission or business requirements and operational needs of organizations. An example of dynamic privilege management is the immediate revocation of privileges from users, as opposed to requiring that users terminate and restart their sessions to reflect changes in privileges. Dynamic privilege management can also include mechanisms that change user privileges based on dynamic rules as opposed to editing specific user profiles. Examples include automatic adjustments of user privileges if they are operating out of their normal work times, their job function or assignment changes, or if systems are under duress or in emergency situations. Dynamic privilege management includes the effects of privilege changes, for example, when there are changes to encryption keys used for communications.

1.10 Control or Control Enhancement Identifier

AC-2(7)

1.10.1 Control or Control Name

Account Management | Privileged User Accounts

1.10.2 Control Text

(a) Establish and administer privileged user accounts in accordance with [Selection: a role-based access scheme; an attribute-based access scheme];

(b) Monitor privileged role or attribute assignments;

(c) Monitor changes to roles or attributes; and

(d) Revoke access when privileged role or attribute assignments are no longer appropriate.

1.10.3 Discussion

Privileged roles are organization-defined roles assigned to individuals that allow those individuals to perform certain security-relevant functions that ordinary users are not authorized to perform. Privileged roles include key management, account management, database administration, system and network administration, and web administration. A role-based access scheme organizes permitted system access and privileges into roles. In contrast, an attribute-based access scheme specifies allowed system access and privileges based on attributes.

AC-2(11)

1.14.1 Control or Control Name

Account Management | Usage Conditions

1.14.2 Control Text

Enforce [Assignment: organization-defined circumstances and/or usage conditions] for [Assignment: organization-defined system accounts].

1.14.3 Discussion

Specifying and enforcing usage conditions helps to enforce the principle of least privilege, increase user accountability, and enable effective account monitoring. Account monitoring includes alerts generated if the account is used in violation of organizational parameters. Organizations can describe specific conditions or circumstances under which system accounts can be used, for example, by restricting usage to certain days of the week, time of day, or specific durations of time.

1.14.4 Related Controls

1.14.5 Audit

The Palo Alto NGFW does not allow under-priviledged actions by a particular user/group. In the GUI, certain non-permitted functions will be greyed out as to deny the user that capability. So there will not be a log event for an attempt to essentially escalate privileges as the user is unable to perform them at all. In the Monitor->Configuration section, there is a Results section which will state Success or Fail. Fail could be for many reasons such as unauthorized or the configuration is invalid.

AC-2(12)

1.15.1 Control or Control Name

Account Management | Account Monitoring for Atypical Usage

1.15.2 Control Text

(a) Monitor system accounts for [Assignment: organization-defined atypical usage]; and

(b) Report atypical usage of system accounts to [Assignment: organization-defined personnel or roles].

1.15.3 Discussion

Atypical usage includes accessing systems at certain times of the day or from locations that are not consistent with the normal usage patterns of individuals working in organizations. Account monitoring may inadvertently create privacy risks. Data collected to identify atypical usage may reveal previously unknown information about the behavior of individuals. Organizations assess and document privacy risks from monitoring accounts for atypical usage in their privacy impact assessment and make determinations that are in alignment with their privacy program plan.

Access Enforcement

1.18.2 Control Text

Enforce approved authorizations for logical access to information and system resources in accordance with applicable access control policies.

1.18.3 Discussion

Access control policies control access between active entities or subjects (i.e., users or processes acting on behalf of users) and passive entities or objects (i.e., devices, files, records, domains) in organizational systems. In addition to enforcing authorized access at the system level and recognizing that systems can host many applications and services in support of missions and business functions, access enforcement mechanisms can also be employed at the application and service level to provide increased information security and privacy. In contrast to logical access controls that are implemented within the system, physical access controls are addressed by the controls in the Physical and Environmental Protection (PE) family.

1.18.4 Related Controls

Access Enforcement | Dual Authorization

1.20.2 Control Text

Enforce dual authorization for [Assignment: organization-defined privileged commands and/or other organization-defined actions].

1.20.3 Discussion

Dual authorization, also known as two-person control, reduces risk related to insider threat. Dual authorization mechanisms require the approval of two authorized individuals to execute. To reduce the risk of collusion, organizations consider rotating dual authorization duties to other individuals. Organizations do not require dual authorization mechanisms when immediate responses are necessary to ensure public and environmental safety.

1.20.4 Related Controls

.

1.20.5 Audit

A workflow approval of changes is not currently supported in Panorama as of 1/21/2021. This control should be monitord for imporvements on the Panorama side. As a workaround, RBAC could be used in Panaroma to disallow administrators from pushing config changes to devices. Only allow admins to 'save to Panorama.' Then in a maintanence window, once approved, and superadmin could push the changes to the devices.

1.20.6 Remediation

Check for RBAC's on Panorama where one user cannot push the policy to the devices.

1.20.7 Products

NGFW,Panorama

1.21 Control or Control Enhancement Identifier

AC-3(3)

1.21.1 Control or Control Name

Access Enforcement | Mandatory Access Control

1.21.2 Control Text

Enforce [Assignment: organization-defined mandatory access control policy] over the set of covered subjects and objects specified in the policy, and where the policy: (a) Is uniformly enforced across the covered subjects and objects within the system; (b) Specifies that a subject that has been granted access to information is constrained from doing any of the following; (1) Passing the information to unauthorized subjects or objects; (2) Granting its privileges to other subjects; (3) Changing one or more security attributes (specified by the policy) on subjects, objects, the system, or system components; (4) Choosing the security attributes and attribute values (specified by the policy) to be associated with newly created or modified objects; and (5) Changing the rules governing access control; and (c) Specifies that [Assignment: organization-defined subjects] may explicitly be granted [Assignment: organization-defined privileges] such that they are not limited by any defined subset (or all) of the above constraints.

1.21.3 Discussion

Mandatory access control is a type of nondiscretionary access control. Mandatory access control policies constrain what actions subjects can take with information obtained from objects for which they have already been granted access. This prevents the subjects from passing the information to unauthorized subjects and objects. Mandatory access control policies constrain actions subjects can take with respect to the propagation of access control privileges; that is, a subject with a privilege cannot pass that privilege to other subjects. The policy is uniformly enforced over all subjects and objects to which the system has control; otherwise, the access control policy can be circumvented. This enforcement is provided by an implementation that meets the reference monitor concept as described in AC-25. The policy is bounded by the system (i.e., once the information is passed outside of the control of the system, additional means may be required to ensure that the constraints on the information remain in effect). The trusted subjects described above are granted privileges consistent with the concept of least privilege (see AC-6). Trusted subjects are only given the minimum privileges relative to the above policy necessary for satisfying organizational mission/business needs. The control is most applicable when there is a mandate that establishes a policy regarding access to controlled unclassified information or classified information and some users of the system are not authorized access to all such information resident in the system. Mandatory access control can operate in conjunction with discretionary access control as described in AC-3(4). A subject constrained in its operation by policies governed by this control can still operate under the less rigorous constraints of AC-3(4), but mandatory access control policies take precedence over the less rigorous constraints of AC-3(4). For example, while a mandatory access control policy imposes a constraint preventing a subject from passing information to another subject operating at a different sensitivity level, AC-3(4) permits the subject to pass the information to any subject with the same sensitivity level as the subject. Examples of mandatory access control policies include the Bell-La Padula policy to protect confidentiality of information and the Biba policy to protect the integrity of information.

N/A

1.22 Control or Control Enhancement Identifier

AC-3(4)

1.22.1 Control or Control Name

Access Enforcement | Discretionary Access Control

1.22.2 Control Text

Enforce [Assignment: organization-defined discretionary access control policy] over the set of covered subjects and objects specified in the policy, and where the policy specifies that a subject that has been granted access to information can do one or more of the following: (a) Pass the information to any other subjects or objects; (b) Grant its privileges to other subjects; (c) Change security attributes on subjects, objects, the system, or the system's components; (d) Choose the security attributes to be associated with newly created or revised objects; or (e) Change the rules governing access control.

1.22.3 Discussion

When discretionary access control policies are implemented, subjects are not constrained regarding what actions they can take with information for which they have already been granted access. Thus, subjects that have been granted access to information are not prevented from passing the information to other subjects or objects (i.e., subjects have the discretion to pass). Discretionary access control can operate in conjunction with mandatory access control as described in AC-3(3) and AC-3(15). A subject that is constrained in its operation by mandatory access control policies can still operate under the less rigorous constraints of discretionary access control. Therefore, while AC-3(3) imposes constraints preventing a subject from passing information to another subject operating at a different sensitivity level, AC-3(4) permits the subject to pass the information to any subject at the same sensitivity level. The policy is bounded by the system. Once the information is passed outside of system control, additional means may be required to ensure that the constraints remain in effect. While traditional definitions of discretionary access control require identity-based access control, that limitation is not required for this particular use of discretionary access control.

Access Enforcement | Security-relevant Information

1.23.2 Control Text

Prevent access to [Assignment: organization-defined security-relevant information] except during secure, non-operable system states.

1.23.3 Discussion

Security-relevant information is information within systems that can potentially impact the operation of security functions or the provision of security services in a manner that could result in failure to enforce system security policies or maintain the separation of code and data. Security-relevant information includes access control lists, filtering rules for routers or firewalls, configuration parameters for security services, and cryptographic key management information. Secure, non-operable system states include the times in which systems are not performing mission or business-related processing such as when the system is off-line for maintenance, boot-up, troubleshooting, or shut down.

Enforce a role-based access control policy over defined subjects and objects and control access based upon [Assignment: organization-defined roles and users authorized to assume such roles].

1.25.3 Discussion

Role-based access control (RBAC) is an access control policy that enforces access to objects and system functions based on the defined role (i.e., job function) of the subject. Organizations can create specific roles based on job functions and the authorizations (i.e., privileges) to perform needed operations on the systems associated with the organization-defined roles. When users are assigned to the specific roles, they inherit the authorizations or privileges defined for those roles. RBAC simplifies privilege administration for because privileges are not assigned directly to every user (which can potentially be a large number of individuals) but are instead acquired through role assignments. RBAC can be implemented as a mandatory or discretionary form of access control. For those organizations implementing RBAC with mandatory access controls, the requirements in AC-3(3) define the scope of the subjects and objects covered by the policy.

1.25.4 Related Controls

1.25.5 Audit

The Palo Alto NGFW supports RBAC for users and groups. During an audit, we should print out the various groups and permissions of such groups.

1.25.6 Remediation

Print out all the users on the firewall and thier groups.

1.26.1 Control or Control Name

Access Enforcement | Revocation of Access Authorizations

1.26.2 Control Text

Enforce the revocation of access authorizations resulting from changes to the security attributes of subjects and objects based on [Assignment: organization-defined rules governing the timing of revocations of access authorizations].

1.26.3 Discussion

Revocation of access rules may differ based on the types of access revoked. For example, if a subject (i.e., user or process acting on behalf of a user) is removed from a group, access may not be revoked until the next time the object is opened or the next time the subject attempts a new access to the object. Revocation based on changes to security labels may take effect immediately. Organizations provide alternative approaches on how to make revocations immediate if systems cannot provide such capability and immediate revocation is necessary.

1.26.4 Related Controls

1.26.5 Audit

This is a procedural control. The Palo Alto NGFW can support the removal of a user of a group, but this control cannot be directly audited on the NGFW. This is a procedural control.

AC-3(9)

1.27.1 Control or Control Name

Access Enforcement | Controlled Release

1.27.2 Control Text

Release information outside of the system only if: (a) The receiving [Assignment: organization-defined system or system component] provides [Assignment: organization-defined controls]; and (b) [Assignment: organization-defined controls] are used to validate the appropriateness of the information designated for release.

1.27.3 Discussion

Systems can only protect organizational information within the confines of established system boundaries. Additional controls may be needed to ensure that such information is adequately protected once it is passed beyond the established system boundaries. In situations where the system is unable to determine the adequacy of the protections provided by external entities, as a mitigating control, organizations determine procedurally whether the external systems are providing adequate controls. The means used to determine the adequacy of controls provided by external systems include conducting periodic assessments (inspections/tests); establishing agreements between the organization and its counterpart organizations; or some other process. The means used by external entities to protect the information received need not be the same as those used by the organization, but the means employed are sufficient to provide

consistent adjudication of the security and privacy policy to protect the information and individuals' privacy. Controlled release of information requires systems to implement technical or procedural means to validate the information prior to releasing it to external systems. For example, if the system passes information to a system controlled by another organization, technical means are employed to validate that the security and privacy attributes associated with the exported information are appropriate for the receiving system. Alternatively, if the system passes information to a printer in organization-controlled space, procedural means can be employed to ensure that only authorized individuals gain access to the printer.

1.31.1 Control or Control Name

Access Enforcement | Attribute-based Access Control

1.31.2 Control Text

Enforce attribute-based access control policy over defined subjects and objects and control access based upon [Assignment: organization-defined attributes to assume access permissions].

1.31.3 Discussion

Attribute-based access control is an access control policy that restricts system access to authorized users based on specified organizational attributes (e.g., job function, identity); action attributes (e.g., read, write, delete); environmental attributes (e.g., time of day, location); and resource attributes (e.g., classification of a document). Organizations can create rules based on attributes and the authorizations (i.e., privileges) to perform needed operations on the systems associated with the organization-defined attributes and rules. When users are assigned to attributes defined in attribute-based access control policies or rules, they can be provisioned to a system with the appropriate privileges or dynamically granted access to a protected resource upon access. Attribute-based access control can be implemented as a mandatory or discretionary form of access control. For attribute-based access control implemented with mandatory access controls, the requirements in AC-3(3) define the scope of the subjects and objects covered by the policy.

1.31.4 Related Controls

Information Flow Enforcement

1.34.2 Control Text

Enforce approved authorizations for controlling the flow of information within the system and between connected systems based on [Assignment: organization-defined information flow control policies].

1.34.3 Discussion

Information flow control regulates where information can travel within a system and between systems (in contrast to who is allowed to access the information) and without regard to subsequent accesses to that information. Flow control restrictions include blocking external traffic that claims to be from within the organization; keeping export-controlled information from being transmitted in the clear to the Internet; restricting web requests that are not from the internal web proxy server; and limiting information transfers between organizations based on data structures and content. Transferring information between organizations may require an agreement specifying how the information flow is enforced (see CA-3). Transferring information between systems in different security or privacy domains with different security or privacy policies introduces risk that such transfers violate one or more domain security or privacy policies. In such situations, information owners/stewards provide guidance at designated policy enforcement points between connected systems. Organizations consider mandating specific architectural solutions to enforce specific security and privacy policies. Enforcement includes prohibiting information transfers between connected systems (i.e., allowing access only); verifying write permissions before accepting information from another security or privacy domain or connected system; employing hardware mechanisms to enforce one-way information flows; and implementing trustworthy regrading mechanisms to reassign security or privacy attributes and security or privacy labels. Organizations commonly employ information flow control policies and enforcement mechanisms to control the flow of information between designated sources and destinations within systems and between connected systems. Flow control is based on the characteristics of the information and/or the information path. Enforcement occurs, for example, in boundary protection devices that employ rule sets or establish configuration settings that restrict system services, provide a packet-filtering capability based on header information, or message-filtering capability based on message content. Organizations also consider the trustworthiness of filtering and/or inspection mechanisms (i.e., hardware, firmware, and software components) that are critical to information flow enforcement. Control enhancements 3 through 32 primarily address cross-domain solution needs that focus on more advanced filtering techniques, in-depth analysis, and stronger flow enforcement mechanisms implemented in cross-domain products, for example, high-assurance guards. Such capabilities are generally not available in commercial off-the-shelf information technology products. This control also applies to control plane traffic (e.g., routing and DNS).

Information Flow Enforcement | Object Security and Privacy Attributes

1.35.2 Control Text

Use [Assignment: organization-defined security and privacy attributes] associated with [Assignment: organization-defined information, source, and destination objects] to enforce [Assignment: organization-defined information flow control policies] as a basis for flow control decisions.

1.35.3 Discussion

Information flow enforcement mechanisms compare security and privacy attributes associated with information (i.e., data content and structure) and source and destination objects and respond appropriately when the enforcement mechanisms encounter information flows not explicitly allowed by information flow policies. For example, an information object labeled Secret would be allowed to flow to a destination object labeled Secret, but an information object labeled Top Secret would not be allowed to flow to a destination object labeled Secret. A dataset of personally identifiable information may be tagged with restrictions against combining with other types of datasets, and therefore, would not be allowed to flow to the restricted dataset. Security and privacy attributes can also include source and destination addresses employed in traffic filter firewalls. Flow enforcement using explicit security or privacy attributes can be used, for example, to control the release of certain types of information.

1.35.4 Related Controls

1.35.5 Audit

Information Flow Enforcement | Processing Domains

1.36.2 Control Text

Use protected processing domains to enforce [Assignment: organization-defined information flow control policies] as a basis for flow control decisions.

1.36.3 Discussion

Protected processing domains within systems are processing spaces that have controlled interactions with other processing spaces, enabling control of information flows between these spaces and to/from information objects. A protected processing domain can be provided, for example, by implementing domain and type enforcement. In domain and type enforcement, system processes are assigned to domains; information is identified by types; and information flows are controlled based on allowed information accesses (i.e., determined by domain and type), allowed signaling among domains, and allowed process transitions to other domains.

1.42.2 Control Text

(a) Enforce information flow control using [Assignment: organization-defined security or privacy policy filters] as a basis for flow control decisions for [Assignment: organization-defined information flows]; and

(b) [Selection (one or more): block; strip; modify; quarantine] data after a filter processing failure in accordance with [Assignment: organization-defined security or privacy policy].

1.42.3 Discussion

Organization-defined security or privacy policy filters can address data structures and content. For example, security or privacy policy filters for data structures can check for maximum file lengths, maximum field sizes, and data/file types (for structured and unstructured data). Security or privacy policy filters for data content can check for specific words enumerated values or data value ranges, and hidden content. Structured data permits the interpretation of data content by applications. Unstructured data refers to digital information without a data structure or with a data structure that does not facilitate the development of rule sets to address the sensitivity of the information conveyed by the data or the flow enforcement decisions. Unstructured data consists of bitmap objects that are inherently non-language-based (i.e., image, video, or audio files); and textual objects that are based on written or printed languages. Organizations can implement more than one security or privacy policy filter to meet information flow control objectives.

Information Flow Enforcement | Data Type Identifiers

1.46.2 Control Text

When transferring information between different security or privacy domains, use [Assignment: organization-defined data type identifiers] to validate data essential for information flow decisions.

1.46.3 Discussion

Data type identifiers include filenames, file types, file signatures or tokens, and multiple internal file signatures or tokens. Systems allow transfer of data only if compliant with data type format specifications. Identification and validation of data types is based on defined specifications associated with each allowed data format. The filename and number alone are not used for data type identification. Content is validated syntactically and semantically against its specification to ensure it is the proper data type.

1.46.4 Related Controls

1.46.5 Audit

File Blocking Profiles allow you to identify specific file types that you want to want to block or monitor. For most traffic (including traffic on your internal network) you will want to block files that are known to carry threats or that have no real use case for upload/download. Currently, these include batch files, DLLs, Java class files, help files, Windows shortcuts (.lnk), and BitTorrent files. Additionally, to provide drive-by download protection, allow download/upload of executables and archive files (.zip and .rar), but force users to acknowledge that they are transferring a file so that they will notice that the browser is attempting to download something they were not aware of. For policy rules that allow general web browsing, be more strict with your file blocking because the risk of users unknowingly downloading malicious files is much higher. For this type of traffic you will want to attach a more strict file blocking profile that also blocks portable executable (PE) files.

Uniquely identify and authenticate source and destination points by [Selection (one or more): organization; system; application; service; individual] for information transfer.

1.51.3 Discussion

Attribution is a critical component of a security and privacy concept of operations. The ability to identify source and destination points for information flowing within systems, allows the forensic reconstruction of events, and encourages policy compliance by attributing policy violations to specific organizations or individuals. Successful domain authentication requires that system labels distinguish among systems, organizations, and individuals involved in preparing, sending, receiving, or disseminating information. Attribution also allows organizations to better maintain the lineage of personally identifiable information processing as it flows through systems and can facilitate consent tracking, as well as correction, deletion, or access requests from individuals.

Information Flow Enforcement | Audit Filtering Actions

1.60.2 Control Text

When transferring information between different security domains, record and audit content filtering actions and results for the information being filtered.

1.60.3 Discussion

Content filtering is the process of inspecting information as it traverses a cross domain solution and determines if the information meets a pre-defined policy. Content filtering actions and results of filtering actions are recorded for individual messages to ensure the correct filter actions were applied. Content filter reports are used to assist in troubleshooting actions, for example, determining why message content was modified and/or why it failed the filtering process. Audit events are defined in AU-2. Audit records are generated in AU-12.

1.60.4 Related Controls

AU-2, AU-3, AU-12

1.60.5 Audit

Palo Alto Networks URL Filtering protects against web-based threats by giving you a way to safely enable web access while controlling how your users interact with online content. With URL Filtering enabled, all web traffic (HTTP and HTTPS) on any port is compared against the URL filtering database, which contains a listing of millions of websites that have been categorized. You can use these URL categories as a match criteria to enforce security policy. You can also use URL filtering to enforce safe search settings for your users and to Prevent Credential Phishing based on URL category.

1.63.1 Control or Control Name

Information Flow Enforcement | Filter Orchestration Engines

1.63.2 Control Text

When transferring information between different security or privacy domains, employ content filter orchestration engines to ensure that: (a) Content filtering mechanisms successfully complete execution without errors; and (b) Content filtering actions occur in the correct order and comply with [Assignment: organization-defined policy].

1.63.3 Discussion

Content filtering is the process of inspecting information as it traverses a cross domain solution and determines if the information meets a pre-defined security policy. An orchestration engine coordinates the sequencing of activities (manual and automated) in a content filtering process. Errors are defined as either anomalous actions or unexpected termination of the content filter process. This is not the same as a filter failing content due non-compliance with policy. Content filter reports are a commonly used mechanism to ensure expected filtering actions are completed successfully.

Separation of Duties

1.67.2 Control Text

a. Identify and document [Assignment: organization-defined duties of individuals requiring separation]; and

b. Define system access authorizations to support separation of duties.

1.67.3 Discussion

Separation of duties addresses the potential for abuse of authorized privileges and helps to reduce the risk of malevolent activity without collusion. Separation of duties includes dividing mission or business functions and support functions among different individuals or roles; conducting system support functions with different individuals; and ensuring security personnel administering access control functions do not also administer audit functions. Because separation of duty violations can span systems and application domains, organizations consider the entirety of systems and system components when developing policy on separation of duties. This control is enforced through the account management activities in AC-2 and access control mechanisms in AC-3.

Unsuccessful Logon Attempts

1.79.2 Control Text

a. Enforce a limit of [Assignment: organization-defined number] consecutive invalid logon attempts by a user during a [Assignment: organization-defined time-period]; and

b. **Automatically [Selection (one or more): lock the account or node for an [Assignment: organization-defined time-period]** ; lock the account or node until released by an administrator; delay next logon prompt per [Assignment: organization-defined delay algorithm] ; notify system administrator; take other [Assignment: organization-defined action]] when the maximum number of unsuccessful attempts is exceeded.

1.79.3 Discussion

This control applies regardless of whether the logon occurs via a local or network connection. Due to the potential for denial of service, automatic lockouts initiated by systems are usually temporary and automatically release after a predetermined, organization-defined time period. If a delay algorithm is selected, organizations may employ different algorithms for different components of the system based on the capabilities of those components. Responses to unsuccessful logon attempts may be implemented at the operating system and the application levels. Organization-defined actions that may be taken when the number of allowed consecutive invalid logon attempts is exceeded include prompting the user to answer a secret question in addition to the username and password; invoking a lockdown mode with limited user capabilities (instead of full lockout); or comparing the IP address to a list of known IP addresses for the user and then allowing additional logon attempts if the attempts are from a known IP address. Techniques to help prevent brute force attacks in lieu of an automatic system lockout or the execution of delay algorithms support the objective of availability while still protecting against such attacks. Techniques that are effective when used in combination include prompting the user to respond to a secret question before the number of allowed unsuccessful logon attempts is exceeded; allowing users to logon only from specified IP addresses; requiring a CAPTCHA to prevent automated attacks; or applying user profiles such as location, time of day, IP address, device, or MAC address. Automatically unlocking an account after a specified period of time is generally not permitted. However, exceptions may be required based on operational mission or need.

Unsuccessful Logon Attempts | Purge or Wipe Mobile Device

1.81.2 Control Text

Purge or wipe information from [Assignment: organization-defined mobile devices] based on [Assignment: organization-defined purging or wiping requirements and techniques] after [Assignment: organization-defined number] consecutive, unsuccessful device logon attempts.

1.81.3 Discussion

A mobile device is a computing device that has a small form factor such that it can be carried by a single individual; is designed to operate without a physical connection; possesses local, non-removable or removable data storage; and includes a self-contained power source. Purging or wiping the device applies only to mobile devices for which the organization-defined number of unsuccessful logons occurs. The logon is to the mobile device, not to any one account on the device. Successful logons to accounts on mobile devices reset the unsuccessful logon count to zero. Purging or wiping may be unnecessary if the information on the device is protected with sufficiently strong encryption mechanisms.

System Use Notification

1.84.2 Control Text

a. Display [Assignment: organization-defined system use notification message or banner] to users before granting access to the system that provides privacy and security notices consistent with applicable laws, executive orders, directives, regulations, policies, standards, and guidelines and state that: 1. Users are accessing a U.S. Government system; 2. System usage may be monitored, recorded, and subject to audit; 3. Unauthorized use of the system is prohibited and subject to criminal and civil penalties; and 4. Use of the system indicates consent to monitoring and recording; b. Retain the notification message or banner on the screen until users acknowledge the usage conditions and take explicit actions to log on to or further access the system; and c. For publicly accessible systems: 1. Display system use information [Assignment: organization-defined conditions], before granting further access to the publicly accessible system; 2. Display references, if any, to monitoring, recording, or auditing that are consistent with privacy accommodations for such systems that generally prohibit those activities; and 3. Include a description of the authorized uses of the system.

1.84.3 Discussion

System use notifications can be implemented using messages or warning banners displayed before individuals log in to systems. System use notifications are used only for access via logon interfaces with human users. Notifications are not required when human interfaces do not exist. Based on an assessment of risk, organizations consider whether or not a secondary system use notification is needed to access applications or other system resources after the initial network logon. Organizations consider system use notification messages or banners displayed in multiple languages based on organizational needs and the demographics of system users. Organizations also consult with the Office of the General Counsel for legal review and approval of warning banner content.

Device Lock

1.91.2 Control Text

a. Prevent further access to the system by [Selection (one or more): initiating a device lock after [Assignment: organization-defined time-period] of inactivity; requiring the user to initiate a device lock before leaving the system unattended]; and

b. Retain the device lock until the user reestablishes access using established identification and authentication procedures.

1.91.3 Discussion

Device locks are temporary actions taken to prevent logical access to organizational systems when users stop work and move away from the immediate vicinity of those systems but do not want to log out because of the temporary nature of their absences. Device locks can be implemented at the operating system level or at the application level. A proximity lock may be used to initiate the device lock (e.g., via a Bluetooth-enabled device or dongle). User initiated device locking is behavior or policy-based and as such, requires users to take physical action to initiate the device lock. Device locks are not an acceptable substitute for logging out of systems, for example, if organizations require users to log out at the end of workdays.

Session Termination

1.93.2 Control Text

Automatically terminate a user session after [Assignment: organization-defined conditions or trigger events requiring session disconnect].

1.93.3 Discussion

Session termination addresses the termination of user-initiated logical sessions (in contrast to SC-10, which addresses the termination of network connections associated with communications sessions (i.e., network disconnect)). A logical session (for local, network, and remote access) is initiated whenever a user (or process acting on behalf of a user) accesses an organizational system. Such user sessions can be terminated without terminating network sessions. Session termination ends all processes associated with a user's logical session except those processes that are specifically created by the user (i.e., session owner) to continue after the session is terminated. Conditions or trigger events requiring automatic session termination include organization-defined periods of user inactivity, targeted responses to certain types of incidents, or time-of-day restrictions on system use.

Permitted Actions Without Identification or Authentication

1.98.2 Control Text

a. Identify [Assignment: organization-defined user actions] that can be performed on the system without identification or authentication consistent with organizational missions and business functions; and

b. Document and provide supporting rationale in the security plan for the system, user actions not requiring identification or authentication.

1.98.3 Discussion

Specific user actions may be permitted without identification or authentication if organizations determine that identification and authentication is not required for the specified user actions. Organizations may allow a limited number of user actions without identification or authentication, including when individuals access public websites or other publicly accessible federal systems; when individuals use mobile phones to receive calls; or when facsimiles are received. Organizations identify actions that normally require identification or authentication but may under certain circumstances, allow identification or authentication mechanisms to be bypassed. Such bypasses may occur, for example, via a software-readable physical switch that commands bypass of the logon functionality and is protected from accidental or unmonitored use. This control does not apply to situations where identification and authentication have already occurred and are not repeated, but rather to situations where identification and authentication have not yet occurred. Organizations may decide that there are no user actions that can be performed on organizational systems without identification and authentication and therefore, the value for the assignment can be none.

Security and Privacy Attributes

1.101.2 Control Text

a. Provide the means to associate [Assignment: organization-defined types of security and privacy attributes] having [Assignment: organization-defined security and privacy attribute values] with information in storage, in process, and/or in transmission;

b. Ensure that the attribute associations are made and retained with the information;

c. Establish the permitted [Assignment: organization-defined security and privacy attributes] for [Assignment: organization-defined systems];

d. Determine the permitted [Assignment: organization-defined values or ranges] for each of the established attributes;

e. Audit changes to attributes; and

f. Review [Assignment: organization-defined security and privacy attributes] for applicability [Assignment: organization-defined frequency].

1.101.3 Discussion

Information is represented internally within systems using abstractions known as data structures. Internal data structures can represent different types of entities, both active and passive. Active entities, also known as subjects, are typically associated with individuals, devices, or processes acting on behalf of individuals. Passive entities, also known as objects, are typically associated with data structures such as records, buffers, tables, files, inter-process pipes, and communications ports. Security attributes, a form of metadata, are abstractions representing the basic properties or characteristics of active and passive entities with respect to safeguarding information. Privacy attributes, which may be used independently, or in conjunction with security attributes, represent the basic properties or characteristics of active or passive entities with respect to the management of personally identifiable information. Attributes can be either explicitly or implicitly associated with the information contained in organizational systems or system components. Attributes may be associated with active entities (i.e., subjects) that have the potential to send or receive information, to cause information to flow among objects, or to change the system state. These attributes may also be associated with passive entities (i.e., objects) that contain or receive information. The association of attributes to subjects and objects by a system is referred to as binding and is inclusive of setting the attribute value and the attribute type. Attributes, when bound to data or information, permit the enforcement of security and privacy policies for access control and information flow control, including data retention limits, permitted uses of personally identifiable information, and identification of personal information within data objects. Such enforcement occurs through organizational processes or system functions or mechanisms. The binding techniques implemented by systems affect the strength of attribute binding to information. Binding strength and the assurance associated with binding techniques play an important part in the trust organizations have in the information flow enforcement process. The binding techniques affect the number and degree of additional reviews required by organizations. The content or assigned values of attributes can directly affect the ability of individuals to access organizational information. Organizations can define the types of attributes needed for systems to support missions or business functions. There are many values that can be assigned to a security attribute. Release markings include US only, NATO (North Atlantic Treaty Organization), or NOFORN (not releasable to foreign nationals). By specifying the permitted attribute ranges and values, organizations ensure that attribute values are meaningful and relevant. Labeling refers to the association of attributes with the subjects and objects represented by the internal data structures within systems. This facilitates system-based enforcement of information security and privacy policies. Labels include classification of information in accordance with legal and compliance requirements; access authorizations; nationality; data life cycle protection (i.e., encryption and data expiration); personally identifiable information processing permissions; individual consent to personally identifiable information processing; and affiliation as a contractor. Conversely, marking refers to the association of attributes with objects in a human-readable form. Marking enables manual, procedural, or process-based enforcement of information security and privacy policies. Attribute types include classification level for objects and clearance (access authorization) level for subjects. An attribute value for both attribute types is Top Secret.

Security and Privacy Attributes | Association of Attributes by Authorized Individuals

1.105.2 Control Text

Provide the capability to associate [Assignment: organization-defined security and privacy attributes] with [Assignment: organization-defined subjects and objects] by authorized individuals (or processes acting on behalf of individuals).

1.105.3 Discussion

Systems in general, provide the capability for privileged users to assign security and privacy attributes to system-defined subjects (e.g., users) and objects (e.g., directories, files, and ports). Some systems provide additional capability for general users to assign security and privacy attributes to additional objects (e.g., files, emails). The association of attributes by authorized individuals is described in the design documentation. The support provided by systems can include prompting users to select security and privacy attributes to be associated with information objects; employing automated mechanisms to categorize information with attributes based on defined policies; or ensuring that the combination of the security or privacy attributes selected is valid. Organizations consider the creation, deletion, or modification of attributes when defining auditable events.

Security and Privacy Attributes | Association Techniques and Technologies

1.109.2 Control Text

Implement [Assignment: organization-defined techniques and technologies] with [Assignment: organization-defined level of assurance] in associating security and privacy attributes to information.

1.109.3 Discussion

The association of security and privacy attributes to information within systems is important for conducting automated access enforcement and flow enforcement actions. The association of such attributes to information (i.e., binding) can be accomplished with technologies and techniques providing different levels of assurance. For example, systems can bind attributes to information cryptographically using digital signatures supporting cryptographic keys protected by hardware devices (sometimes known as hardware roots of trust).

Security and Privacy Attributes | Attribute Reassignment — Regrading Mechanisms

1.110.2 Control Text

Change security and privacy attributes associated with information only via regrading mechanisms validated using [Assignment: organization-defined techniques or procedures].

1.110.3 Discussion

A regrading mechanism is a trusted process authorized to re-classify and re-label data in accordance with a defined policy exception. Validated regrading mechanisms are used by organizations to provide the requisite levels of assurance for attribute reassignment activities. The validation is facilitated by ensuring that regrading mechanisms are single purpose and of limited function. Since security and privacy attribute changes can directly affect policy enforcement actions, implementing trustworthy regrading mechanisms is necessary to help ensure that such mechanisms perform in a consistent and correct mode of operation.

Remote Access

1.112.2 Control Text

a. Establish and document usage restrictions, configuration/connection requirements, and implementation guidance for each type of remote access allowed; and

b. Authorize each type of remote access to the system prior to allowing such connections.

1.112.3 Discussion

Remote access is access to organizational systems (or processes acting on behalf of users) communicating through external networks such as the Internet. Types of remote access include dial-up, broadband, and wireless. Organizations use encrypted virtual private networks (VPNs) to enhance confidentiality and integrity for remote connections. The use of encrypted VPNs provides sufficient assurance to the organization that it can effectively treat such connections as internal networks if the cryptographic mechanisms used are implemented in accordance with applicable laws, executive orders, directives, regulations, policies, standards, and guidelines. Still, VPN connections traverse external networks, and the encrypted VPN does not enhance the availability of remote connections. VPNs with encrypted tunnels can also affect the capability to adequately monitor network communications traffic for malicious code. Remote access controls apply to systems other than public web servers or systems designed for public access. This control addresses authorization prior to allowing remote access without specifying the specific formats for such authorization. While organizations may use information exchange and system connection security agreements to authorize remote access connections, such agreements are not required by this control. Enforcing access restrictions for remote access is addressed via AC-3.

Remote Access | Monitoring and Control

1.113.2 Control Text

Employ automated mechanisms to monitor and control remote access methods.

1.113.3 Discussion

Monitoring and control of remote access methods allows organizations to detect attacks and ensure compliance with remote access policies by auditing connection activities of remote users on a variety of system components, including servers, notebook computers, workstations, smart phones, and tablets. Audit logging for remote access is enforced by AU-2. Audit events are defined in AU-2a.

1.113.4 Related Controls

AU-2, AU-6, AU-12, AU-14

1.113.5 Audit

One of the jobs of the GlobalProtect app is to collect information about the host it is running on. The app then submits this host information to the GlobalProtect gateway upon successful connection. The gateway matches this raw host information submitted by the app against any HIP objects and HIP profiles that you have defined. If it finds a match, it generates an entry in the HIP Match log. Additionally, if it finds a HIP profile match in a policy rule, it enforces the corresponding security policy.

Remote Access | Authenticate Remote Commands

1.122.2 Control Text

Implement [Assignment: organization-defined controls] to authenticate [Assignment: organization-defined remote commands].

1.122.3 Discussion

Authenticating remote commands protects against unauthorized commands and the replay of authorized commands. The capability to authenticate remote commands is important for remote systems whose loss, malfunction, misdirection, or exploitation would have immediate or serious consequences, including injury or death; property damage; loss of high value assets; failure of missions or business functions; or compromise of classified or controlled unclassified information. Authentication controls for remote commands ensure that systems accept and execute commands in the order intended, execute only authorized commands, and reject unauthorized commands. Cryptographic mechanisms can be used, for example, to authenticate remote commands.

Wireless Access | Antennas and Transmission Power Levels

1.128.2 Control Text

Select radio antennas and calibrate transmission power levels to reduce the probability that signals from wireless access points can be received outside of organization-controlled boundaries.

1.128.3 Discussion

Actions that may be taken to limit unauthorized use of wireless communications outside of organization-controlled boundaries include reducing the power of wireless transmissions so that the transmissions are less likely to emit a signal that can be captured outside of the physical perimeters of the organization; employing measures such as emissions security to control wireless emanations; and using directional or beam forming antennas that reduce the likelihood that unintended receivers will be able to intercept signals. Prior to taking such mitigating actions, organizations can conduct periodic wireless surveys to understand the radio frequency profile of organizational systems as well as other systems that may be operating in the area.

Access Control for Mobile Devices

1.129.2 Control Text

a. Establish configuration requirements, connection requirements, and implementation guidance for organization-controlled mobile devices, to include when such devices are outside of controlled areas; and

b. Authorize the connection of mobile devices to organizational systems.

1.129.3 Discussion

A mobile device is a computing device that has a small form factor such that it can easily be carried by a single individual; is designed to operate without a physical connection; possesses local, non-removable or removable data storage; and includes a self-contained power source. Mobile device functionality may also include voice communication capabilities, on-board sensors that allow the device to capture information, and/or built-in features for synchronizing local data with remote locations. Examples include smart phones and tablets. Mobile devices are typically associated with a single individual. The processing, storage, and transmission capability of the mobile device may be comparable to or merely a subset of notebook/desktop systems, depending upon the nature and intended purpose of the device. Protection and control of mobile devices is behavior or policy-based and requires users to take physical action to protect and control such devices when outside of controlled areas. Controlled areas are spaces for which organizations provide physical or procedural controls to meet the requirements established for protecting information and systems. Due to the large variety of mobile devices with different characteristics and capabilities, organizational restrictions may vary for the different classes or types of such devices. Usage restrictions and specific implementation guidance for mobile devices include configuration management, device identification and authentication, implementation of mandatory protective software, scanning devices for malicious code, updating virus protection software, scanning for critical software updates and patches, conducting primary operating system (and possibly other resident software) integrity checks, and disabling unnecessary hardware. Usage restrictions and authorization to connect may vary among organizational systems. For example, the organization may authorize the connection of mobile devices to the organizational network and impose a set of usage restrictions while a system owner may withhold authorization for mobile device connection to specific applications or may impose additional usage restrictions before allowing mobile device connections to a system. The need to provide adequate security for mobile devices goes beyond the requirements in this control. Many controls for mobile devices are reflected in other controls allocated to the initial control baselines as starting points for the development of security plans and overlays using the tailoring process. There may also be some overlap by the security controls within the different families of controls. AC-20 addresses mobile devices that are not organization-controlled.

Use of External Systems

1.135.2 Control Text

Establish [Selection (one or more):

[Assignment: organization-defined terms and conditions]

; [Assignment: organization-defined controls asserted to be implemented on external systems]

], consistent with the trust relationships established with other organizations owning, operating, and/or maintaining external systems, allowing authorized individuals to:

a. Access the system from external systems; and

b. Process, store, or transmit organization-controlled information using external systems.

1.135.3 Discussion

External systems are systems that are used by, but not a part of, organizational systems and for which the organization has no direct control over the implementation of required security and privacy controls or the assessment of control effectiveness. External systems include personally owned systems, components, or devices; privately owned computing and communications devices in commercial or public facilities; systems owned or controlled by nonfederal organizations; systems managed by contractors; and federal information systems that are not owned by, operated by, or under the direct supervision and authority of the organization. External systems also include systems owned or operated by other components within the same organization, and systems within the organization with different authorization boundaries. For some external systems (i.e., systems operated by other organizations), the trust relationships that have been established between those organizations and the originating organization may be such, that no explicit terms and conditions are required. Systems within these organizations may not be considered external. These situations occur when, for example, there are pre-existing information exchange agreements (either implicit or explicit) established between organizations or components, or when such agreements are specified by applicable laws, executive orders, directives, regulations, policies, or standards. Authorized individuals include organizational personnel, contractors, or other individuals with authorized access to organizational systems and over which organizations have the authority to impose specific rules of behavior regarding system access. Restrictions that organizations impose on authorized individuals need not be uniform, as the restrictions may vary depending on trust relationships between organizations. Therefore, organizations may choose to impose different security restrictions on contractors than on state, local, or tribal governments. This control does not apply to external systems used to access public interfaces to organizational

systems. Organizations establish specific terms and conditions for the use of external systems in accordance with organizational security policies and procedures. Terms and conditions address as a minimum: the specific types of applications that can be accessed on organizational systems from external systems; and the highest security category of information that can be processed, stored, or transmitted on external systems. If the terms and conditions with the owners of the external systems cannot be established, organizations may impose restrictions on organizational personnel using those external systems.

Use of External Systems | Limits on Authorized Use

1.136.2 Control Text

Permit authorized individuals to use an external system to access the system or to process, store, or transmit organization-controlled information only after: (a) Verification of the implementation of controls on the external system as specified in the organization's security and privacy policies and security and privacy plans; or (b) Retention of approved system connection or processing agreements with the organizational entity hosting the external system.

1.136.3 Discussion

Limits on authorized use recognizes the circumstances where individuals using external systems may need to access organizational systems. Organizations need assurance that the external systems contain the necessary controls so as not to compromise, damage, or otherwise harm organizational systems. Verification that the required controls have been implemented can be achieved by external, independent assessments, attestations, or other means, depending on the confidence level required by organizations.

Restrict the use of non-organizationally owned systems or system components to process, store, or transmit organizational information using [Assignment: organization-defined restrictions].

1.138.3 Discussion

Non-organizationally owned systems or system components include systems or system components owned by other organizations and personally owned devices. There are potential risks to using non-organizationally owned systems or system components. In some cases, the risk is sufficiently high as to prohibit such use (see AC-20(6)). In other cases, the use of such systems or system components may be allowed but restricted in some way. Restrictions include requiring the implementation of approved controls prior to authorizing connection of non-organizationally owned systems and components; limiting access to types of information, services, or applications; using virtualization techniques to limit processing and storage activities to servers or system components provisioned by the organization; and agreeing to the terms and conditions for usage. Organizations consult with the Office of the General Counsel regarding legal issues associated with using personally owned devices, including requirements for conducting forensic analyses during investigations after an incident.

Information Sharing

1.142.2 Control Text

a. Enable authorized users to determine whether access authorizations assigned to a sharing partner match the information's access and use restrictions for [Assignment: organization-defined information sharing circumstances where user discretion is required]; and

b. Employ [Assignment: organization-defined automated mechanisms or manual processes] to assist users in making information sharing and collaboration decisions.

1.142.3 Discussion

Information sharing applies to information that may be restricted in some manner based on some formal or administrative determination. Examples of such information include, contract-sensitive information, classified information related to special access programs or compartments, privileged information, proprietary information, and personally identifiable information. Security and privacy risk assessments as well as applicable laws, regulations, and policies can provide useful inputs to these determinations. Depending on the circumstances, sharing partners may be defined at the individual, group, or organizational level. Information may be defined by content, type, security category, or special access program or compartment. Access restrictions may include non-disclosure agreements (NDA).

Publicly Accessible Content

1.145.2 Control Text

a. Designate individuals authorized to make information publicly accessible;

b. Train authorized individuals to ensure that publicly accessible information does not contain nonpublic information;

c. Review the proposed content of information prior to posting onto the publicly accessible system to ensure that nonpublic information is not included; and

d. Review the content on the publicly accessible system for nonpublic information [Assignment: organization-defined frequency] and remove such information, if discovered.

1.145.3 Discussion

In accordance with applicable laws, executive orders, directives, policies, regulations, standards, and guidelines, the public is not authorized to have access to nonpublic information, including information protected under the [PRIVACT] and proprietary information. This control addresses systems that are controlled by the organization and accessible to the public, typically without identification or authentication. Posting information on non-organizational systems (e.g., non-organizational public websites, forums, and social media) is covered by organizational policy. While organizations may have individuals who are responsible for developing and implementing policies about the information that can be made publicly accessible, this control addresses the management of the individuals who make such information publicly accessible.

Data Mining Protection

1.146.2 Control Text

Employ [Assignment: organization-defined data mining prevention and detection techniques] for [Assignment: organization-defined data storage objects] to detect and protect against unauthorized data mining.

1.146.3 Discussion

Data mining is an analytical process that attempts to find correlations or patterns in large data sets for the purpose of data or knowledge discovery. Data storage objects include database records and database fields. Sensitive information can be extracted from data mining operations. When information is personally identifiable information, it may lead to unanticipated revelations about individuals and give rise to privacy risks. Prior to performing data mining activities, organizations determine whether such activities are authorized. Organizations may be subject to applicable laws, executive orders, directives, regulations, or policies that address data mining requirements. Organizational personnel consult with the senior agency official for privacy and legal counsel regarding such requirements. Data mining prevention and detection techniques include limiting the number and the frequency of database queries to increase the work factor needed to determine the contents of such databases; limiting types of responses provided to database queries; applying differential privacy techniques or homomorphic encryption; and notifying personnel when atypical database queries or accesses occur. Data mining protection focuses on protecting information from data mining while such information resides in organizational data stores. In contrast, AU-13 focuses on monitoring for organizational information that may have been mined or otherwise obtained from data stores and is available as open source information residing on external sites, for example, through social networking or social media websites. [EO 13587] requires the establishment of an insider threat program for deterring, detecting, and mitigating insider threats, including the safeguarding of sensitive information from exploitation, compromise, or other unauthorized disclosure. This control requires organizations to identify appropriate techniques to prevent and detect unnecessary or unauthorized data mining, which can be used by an insider to collect organizational information for the purpose of exfiltration.

Access Control Decisions

1.147.2 Control Text

[Selection: Establish procedures; Implement mechanisms] to ensure [Assignment: organization-defined access control decisions] are applied to each access request prior to access enforcement.

1.147.3 Discussion

Access control decisions (also known as authorization decisions) occur when authorization information is applied to specific accesses. In contrast, access enforcement occurs when systems enforce access control decisions. While it is very common to have access control decisions and access enforcement implemented by the same entity, it is not required, and it is not always an optimal implementation choice. For some architectures and distributed systems, different entities may perform access control decisions and access enforcement.

Access Control Decisions | Transmit Access Authorization Information

1.148.2 Control Text

Transmit [Assignment: organization-defined access authorization information] using [Assignment: organization-defined controls] to [Assignment: organization-defined systems] that enforce access control decisions.

1.148.3 Discussion

Authorization processes and access control decisions may occur in separate parts of systems or in separate systems. In such instances, authorization information is transmitted securely (e.g., using cryptographic mechanisms) so timely access control decisions can be enforced at the appropriate locations. To support the access control decisions, it may be necessary to transmit as part of the access authorization information, supporting security and privacy attributes. This is because in distributed systems, there are various access control decisions that need to be made and different entities make these decisions in a serial fashion, each requiring those attributes to make the decisions. Protecting access authorization information ensures that such information cannot be altered, spoofed, or compromised during transmission.

Access Control Decisions | No User or Process Identity

1.149.2 Control Text

Enforce access control decisions based on [Assignment: organization-defined security or privacy attributes] that do not include the identity of the user or process acting on behalf of the user.

1.149.3 Discussion

In certain situations, it is important that access control decisions can be made without information regarding the identity of the users issuing the requests. These are generally instances where preserving individual privacy is of paramount importance. In other situations, user identification information is simply not needed for access control decisions and, especially in the case of distributed systems, transmitting such information with the needed degree of assurance may be very expensive or difficult to accomplish. MAC, RBAC, ABAC, and label-based control policies, for example, might not include user identity as an attribute.

Reference Monitor

1.150.2 Control Text

Implement a reference monitor for [Assignment: organization-defined access control policies] that is tamperproof, always invoked, and small enough to be subject to analysis and testing, the completeness of which can be assured.

1.150.3 Discussion

A reference monitor is a set of design requirements on a reference validation mechanism that as key component of an operating system, enforces an access control policy over all subjects and objects. A reference validation mechanism is always invoked (i.e., complete mediation); tamperproof; and small enough to be subject to analysis and tests, the completeness of which can be assured (i.e., verifiable). Information is represented internally within systems using abstractions known as data structures. Internal data structures can represent different types of entities, both active and passive. Active entities, also known as subjects, are associated with individuals, devices, or processes acting on behalf of individuals. Passive entities, also known as objects, are associated with data structures such as records, buffers, communications ports, tables, files, and inter-process pipes. Reference monitors enforce access control policies that restrict access to objects based on the identity of subjects or groups to which the subjects belong. The system enforces the access control policy based on the rule set established by the policy. The tamperproof property of the reference monitor prevents determined adversaries from compromising the functioning of the mechanism. The always invoked property prevents adversaries from bypassing the mechanism and hence violating the security policy. The smallness property helps to ensure the completeness in the analysis and testing of the mechanism to detect any weaknesses or deficiencies (i.e., latent flaws) that would prevent the enforcement of the security policy.
